

Parity vs. majority (lecture notes)

Course: Circuit Complexity, Autumn 2024, University of Chicago

Instructor: William Hoza (williamhoza@uchicago.edu)

1 Using majority gates to compute the parity function

In a previous class, we showed that $\text{PARITY} \notin \text{AC}^0$. In this section, we will do a *reduction* from the parity function to the majority function. This will imply that $\text{MAJORITY} \notin \text{AC}^0$. More precisely, when we say a “reduction from parity to majority,” we mean a circuit that computes the parity function using majority gates. This motivates the following definition.

Definition 1 (The complexity class TC^0). A function $f: \{0, 1\}^* \rightarrow \{0, 1\}^*$ is in TC^0 if it can be computed by a constant-depth polynomial-size circuit in which every gate is a MAJ gate of unbounded fan-in, and there are literals and constants at the bottom.

The class TC^0 roughly corresponds to *neural networks* in machine learning. We have $\text{AC}^0 \subseteq \text{TC}^0 \subseteq \text{NC}^1$. Our goal is to show that $\text{PARITY} \in \text{TC}^0$. More generally, we will prove that every “symmetric function” is in TC^0 .

Definition 2 (Symmetric Boolean function). A function $f: \{0, 1\}^n \rightarrow \{0, 1\}$ (or $f: \{0, 1\}^* \rightarrow \{0, 1\}$) is *symmetric* if $f(x)$ depends only on the Hamming weight of x . The class of symmetric functions is denoted SYM .

For example, PARITY , MAJ , AND , and OR are all symmetric. The following “threshold functions” are also symmetric:

$$T_n^{\leq k}(x) = 1 \iff \sum_{i=1}^n x_i \leq k$$
$$T_n^{\geq k}(x) = 1 \iff \sum_{i=1}^n x_i \geq k.$$

Lemma 1 (Shifting thresholds). $T_n^{\geq k}$ and $T_n^{\leq k}$ are both in TC^0 .¹

Proof sketch.

$$T_n^{\geq k}(x_1, \dots, x_n) = \text{MAJ}_{2n+2k}(x_1, \dots, x_n, \underbrace{0, \dots, 0}_{2k \text{ zeroes}}, \underbrace{1, \dots, 1}_n),$$

and similarly

$$T_n^{\leq k}(x_1, \dots, x_n) = \text{MAJ}_{2n+2k}(x_1, \dots, x_n, \underbrace{0, \dots, 0}_n, \underbrace{1, \dots, 1}_{2k \text{ ones}}). \quad \square$$

Theorem 1 ($\text{SYM} \subseteq \text{TC}^0$). If $f: \{0, 1\}^* \rightarrow \{0, 1\}$ is symmetric, then $f \in \text{TC}^0$.

Proof. Let $n \in \mathbb{N}$. There is some set $S \subseteq [n]$ such that for every $x \in \{0, 1\}^n$, $f(x) = 1$ if and only if $|x| \in S$, where $|x|$ denotes Hamming weight. Then

$$f(x) = \left(\sum_{k \in S} (T_n^{\leq k}(x) + T_n^{\geq k}(x)) \right) - |S|,$$

which is a threshold of thresholds. \square

¹The function $T_n^{\geq k}$ is parameterized by two values (n and k), so it is not necessarily clear what it means to say that $T_n^{\geq k} \in \text{TC}^0$. The meaning is that $T_n^{\geq k(n)} \in \text{TC}^0$ for every function $k(n)$. Equivalently, for every n and k , there is a constant-depth polynomial-size majority circuit that computes $T_n^{\geq k}$, i.e., the depth and the exponent of the size do not depend on n or k . Similarly with $T_n^{\leq k}$.

Corollary 1 ($\text{MAJ} \notin \text{AC}^0$). *There exists a constant $\alpha > 0$ such that the following holds. Let C be a size- S AC_d^0 circuit computing MAJ_n , where $d \leq \frac{\alpha \log n}{\log \log n}$. Then $S = 2^{n^{\Omega(1/d)}}$.*

Proof. Since $\text{PARITY} \in \text{TC}^0$, there is a constant-depth polynomial-size circuit computing $\text{PARITY}_{n'}$ using MAJ_n gates, where $n' = n^{\Omega(1)}$.² By replacing each MAJ_n gate with a copy of C , we get an $\text{AC}_{O(d)}^0$ circuit computing $\text{PARITY}_{n'}$ of size $S' = S \cdot \text{poly}(n)$. We proved in a previous class that $S' = 2^{(n')^{\Omega(1/d)}} = 2^{n^{\Omega(1/d)}}$. Therefore, $S \geq 2^{n^{\Omega(1/d)}} / \text{poly}(n)$, which is $2^{n^{\Omega(1/d)}}$ if we pick α small enough. \square

2 Majority is hard, even if we are allowed to use parity gates

Definition 3 (The complexity class $\text{AC}^0[m]$). An $\text{AC}_d^0[m]$ circuit is a depth- d circuit in which we can use AND gates, OR gates, and MOD_m gates of unbounded fan-in. A MOD_m gate computes the function

$$\text{MOD}_m(x) = \begin{cases} 0 & \text{if } \sum_i x_i \equiv 0 \pmod{m} \\ 1 & \text{if } \sum_i x_i \not\equiv 0 \pmod{m}. \end{cases}$$

At the bottom, there are literals and constants. (Negations do not count toward the size or depth of the circuit.) A function $f: \{0, 1\}^* \rightarrow \{0, 1\}$ is in $\text{AC}^0[m]$ if it can be computed by constant-depth polynomial-size $\text{AC}^0[m]$ circuits.

For example, a MOD_2 gate computes the parity function. For this reason, $\text{AC}^0[2]$ is also often denoted $\text{AC}^0[\oplus]$. We have

$$\text{AC}^0 \subseteq \text{AC}^0[\oplus] \subseteq \text{TC}^0 \subseteq \text{NC}^1.$$

The first containment is strict ($\text{AC}^0 \neq \text{AC}^0[\oplus]$), because $\text{PARITY} \notin \text{AC}^0$. In this section, we will prove that the second containment is also strict ($\text{AC}^0[\oplus] \neq \text{TC}^0$). This is equivalent to proving that $\text{MAJ} \notin \text{AC}^0[\oplus]$. The first step of the proof is to generalize our probabilistic polynomial construction to $\text{AC}^0[\oplus]$ circuits.

Theorem 2 (Probabilistic polynomials for $\text{AC}^0[\oplus]$). *Let $f: \{0, 1\}^n \rightarrow \{0, 1\}$ be a $\text{AC}_d^0[\oplus]$ circuit of size $S \geq n$, and let $\varepsilon > 0$. Then f can be computed with error ε by a probabilistic polynomial over \mathbb{F}_2 of degree $(\log(S/\varepsilon))^{O(d)}$.*

Proof sketch. Repeat the proof that AC^0 can be simulated by probabilistic polynomials, and use the fact that the parity function can be computed exactly by a degree-1 polynomial over \mathbb{F}_2 . \square

The second step, which is not so easy, is to show that low-degree polynomials over \mathbb{F}_2 cannot approximate the majority function (just like we showed that low-degree polynomials over \mathbb{F}_3 cannot approximate the parity function). Specifically, we will bound the success probability when the input is chosen uniformly at random:

Theorem 3 (Low-degree polynomials over \mathbb{F}_2 have low correlation with the majority function). *If p is an n -variate degree- D polynomial over \mathbb{F}_2 , then*

$$\Pr_{x \in \{0, 1\}^n} [p(x) = \text{MAJ}(x)] \leq \frac{1}{2} + O(D/\sqrt{n}).$$

The first step in the proof of [Theorem 3](#) is to show that if q is a nonzero low-degree polynomial, then every point in \mathbb{F}_2^n is close to a point that q accepts. Let $\Delta(\cdot, \cdot)$ denote Hamming distance.

Lemma 2 (If q has low degree, then every point is close to $q^{-1}(1)$). *Suppose $q: \mathbb{F}_2^n \rightarrow \mathbb{F}_2$ is a nonzero polynomial. Then for every $x \in \mathbb{F}_2^n$, we have $\Delta(x, q^{-1}(1)) \leq \deg(q)$.*

²Here we are using the fact that MAJ_a reduces to MAJ_b whenever $a \leq b$. This is because $\text{MAJ}_a(x) = \text{MAJ}_{a+1}(x_1)$ if a is even, and $\text{MAJ}_a(x) = \text{MAJ}_{a+1}(x_0)$ if a is odd.

Proof. Let $r(y) = q(x + y)$. Then r is another nonzero polynomial with $\deg(r) = \deg(q)$. Let y be the indicator for some minimal nonzero term of r . Then $r(y) = 1$, so $q(x + y) = 1$. \square

Let $B_w(x)$ be the Hamming ball of radius w centered at $x \in \{0, 1\}^n$, i.e., $B_w(x) = \{y : \Delta(x, y) \leq w\}$. Based on [Lemma 2](#), we now show that arbitrary functions on small Hamming balls can be interpolated by low-degree polynomials.

Lemma 3 (Low-degree interpolation on small Hamming balls). *Let $x \in \mathbb{F}_2^n$, let $w \leq n$, and let $f : B_w(x) \rightarrow \mathbb{F}_2$ be any function. There exists a polynomial $q : \mathbb{F}_2^n \rightarrow \mathbb{F}_2$ of degree at most w such that $q(y) = f(y)$ for every $y \in B_w(x)$.*

Proof. Let \mathcal{P} be the space of all n -variate polynomials of degree at most w over \mathbb{F}_2 . Let \mathcal{F} be the space of all functions mapping $B_w(x)$ to \mathbb{F}_2 . Define $\Psi : \mathcal{P} \rightarrow \mathcal{F}$ by the rule $\Psi(q) = q|_{B_w(x)}$, i.e., $\Psi(q)$ is q restricted to $B_w(x)$. Our goal is to prove that Ψ is surjective. Observe that $|\mathcal{P}| = |\mathcal{F}| = 2^{|B_w(x)|}$. Therefore, it is equivalent to show that Ψ is injective, which is what we will do next.

Suppose $\Psi(q_1) = \Psi(q_2)$, i.e., q_1 and q_2 are polynomials of degree at most w that agree on $B_w(x)$. Let $q' := q_1 + q_2$. Then q' is a polynomial of degree at most w that is zero on $B_w(x)$. By [Lemma 2](#), this implies that $q' \equiv 0$, and hence $q_1 \equiv q_2$. \square

Using [Lemma 3](#), we will now show that there is a low-degree reduction from arbitrary functions to the majority function, analogous to our analysis of polynomials approximating PARITY over \mathbb{F}_3 .

Lemma 4 (Low-degree reduction from arbitrary functions to the majority function). *Every function $f : \mathbb{F}_2^n \rightarrow \mathbb{F}_2$ can be written in the form $f(x) = p_0(x) + p_1(x) \cdot \text{Maj}(x)$, where p_0 and p_1 have degree at most $n/2$.*

Proof. Let p_0 agree with f on $B_{\lceil n/2 \rceil - 1}(0^n)$. Let p_1 agree with $f + p_0$ on $B_{\lceil n/2 \rceil}(1^n)$. \square

Proof of Theorem 3. Let $S = \{x : p(x) = \text{Maj}(x)\}$. By [Lemma 4](#), every function $f : S \rightarrow \mathbb{F}_2$ can be written as $f(x) = p_0(x) + p_1(x) \cdot p(x)$, a polynomial of degree at most $n/2 + D$. The number of functions $f : S \rightarrow \mathbb{F}_2$ is $2^{|S|}$. On the other hand, the number of polynomials of degree at most $n/2 + D$ is $2^{\sum_{i=0}^{n/2+D} \binom{n}{i}}$. Therefore, $|S| \leq \sum_{i=0}^{n/2+D} \binom{n}{i} \leq 2^n \cdot (1/2 + O(D/\sqrt{n}))$. \square

Corollary 2 ($\text{MAJ} \notin \text{AC}^0[\oplus]$). *Every $\text{AC}_d^0[\oplus]$ circuit computing MAJ_n has size $2^{n^{\Omega(1/d)}}$.*

Using similar techniques, one can show more generally that $\text{MAJ} \notin \text{AC}^0[m]$ whenever m is a power of a prime. However, when m is composite, these techniques break down. It is an open problem to prove that $\text{MAJ} \notin \text{AC}^0[6]$. In fact, it is an open problem to rule out the ridiculous suggestion that $\text{NP} \subseteq \text{AC}^0[6]$! However, the situation is not completely bleak; there are some known techniques for proving that “somewhat explicit” functions cannot be computed by $\text{AC}^0[6]$ and similar classes. For example, Murray and Williams proved that $\text{NQP} \not\subseteq \text{ACC}$ [MW18], where NQP denotes nondeterministic quasipolynomial time and $\text{ACC} = \bigcup_m \text{AC}^0[m]$.
